Lecture 5
Representation-based Search

This and next lecture

Topics:
- Representation-based search
- Stochastic search

Paper: Rishabh Singh: [BlinkFill: Semisupervised Programming By Example for Syntactic String Transformations](#). VLDB'16

Projects:
- Proposals due next week
- 1 page, PDF or Google Doc
- Upload to Canvas

The problem statement

Behavioral constraints = examples

```
[1,4,7,2,0,6,9,2,5]  →  [1,2,4,7,0]
[0] → [0]
[5,1] → [1,5,0]
```

Search strategy?

Enumerative
Representation-based
Stochastic
Constraint-based

Structural constraints = grammar

```
L ::= sort(L)  |  L[N..N]
       |  L + L  |  [N]  |  x
N ::= find(L,N)  |  0
```

Representation-based search

Idea:

1. build a data structure that compactly represents good parts of the search space
2. extract solution from that data structure

Useful when:

- need to return multiple results / rank the results
- can pre-process search space and use for multiple queries

Representations

Version Space Algebra

Idea: build a data structure that succinctly represents the set of *all* programs consistent with examples
- called a **version space**

Operations on version spaces:
- `learn <i, o> → VS`
- `VS_1 ∩ VS_2 → VS`
- `pick VS → program`

Algorithm:

1. `learn a VS for each example`
2. `intersect them all`
3. `pick any (or best) program`

Version Space Algebra

union node

join node

$\cup$

$F_{\bowtie}$ $F_{\bowtie}$

$\{P_1, \dots, P_k\}$ $\{P_1, \dots, P_k\}$ $\{P_1, \dots, P_k\}$

direct set

example:

$\cup$

$+$ $*$

$\{x, y\}$ $\{2,3\}$

Version Space Algebra

union node

join node

direct set
Volume of a VSA
(the number of nodes) $V(VSA)$

Size of a VSA
(the number of programs) $|VSA|$

$$V(VSA) = O(\log|VSA|)$$

- BlinkFill, FlashExtract, FlashRelate, …
- generalized in the PROSE framework

FlashFill

Simplified grammar:

```
E ::= F | concat(F, E)          "Trace" expression
F ::= cstr(str) | sub(P, P)     Atomic expression
P ::= cpos(num) | pos(R, R)     Position expression
R ::= tokens(T₁, ..., Tₙ)       Regular expression
T ::= C | C+                    Token expression
C ::= ws | digit | alpha | Alpha | $ | ^ | …
```

$E ::= F \mid \text{concat}(F, E)$ — "Trace" expression

$F ::= \text{cstr}(str) \mid \text{sub}(P, P)$ — Atomic expression

$P ::= \text{cpos}(num) \mid \text{pos}(R, R)$ — Position expression

$R ::= \text{tokens}(T_1, ..., T_n)$ — Regular expression

$T ::= C \mid C+$ — Token expression

$C ::= \text{ws} \mid \text{digit} \mid \text{alpha} \mid \text{Alpha} \mid \$ \mid \char94 \mid …$ — Token expression
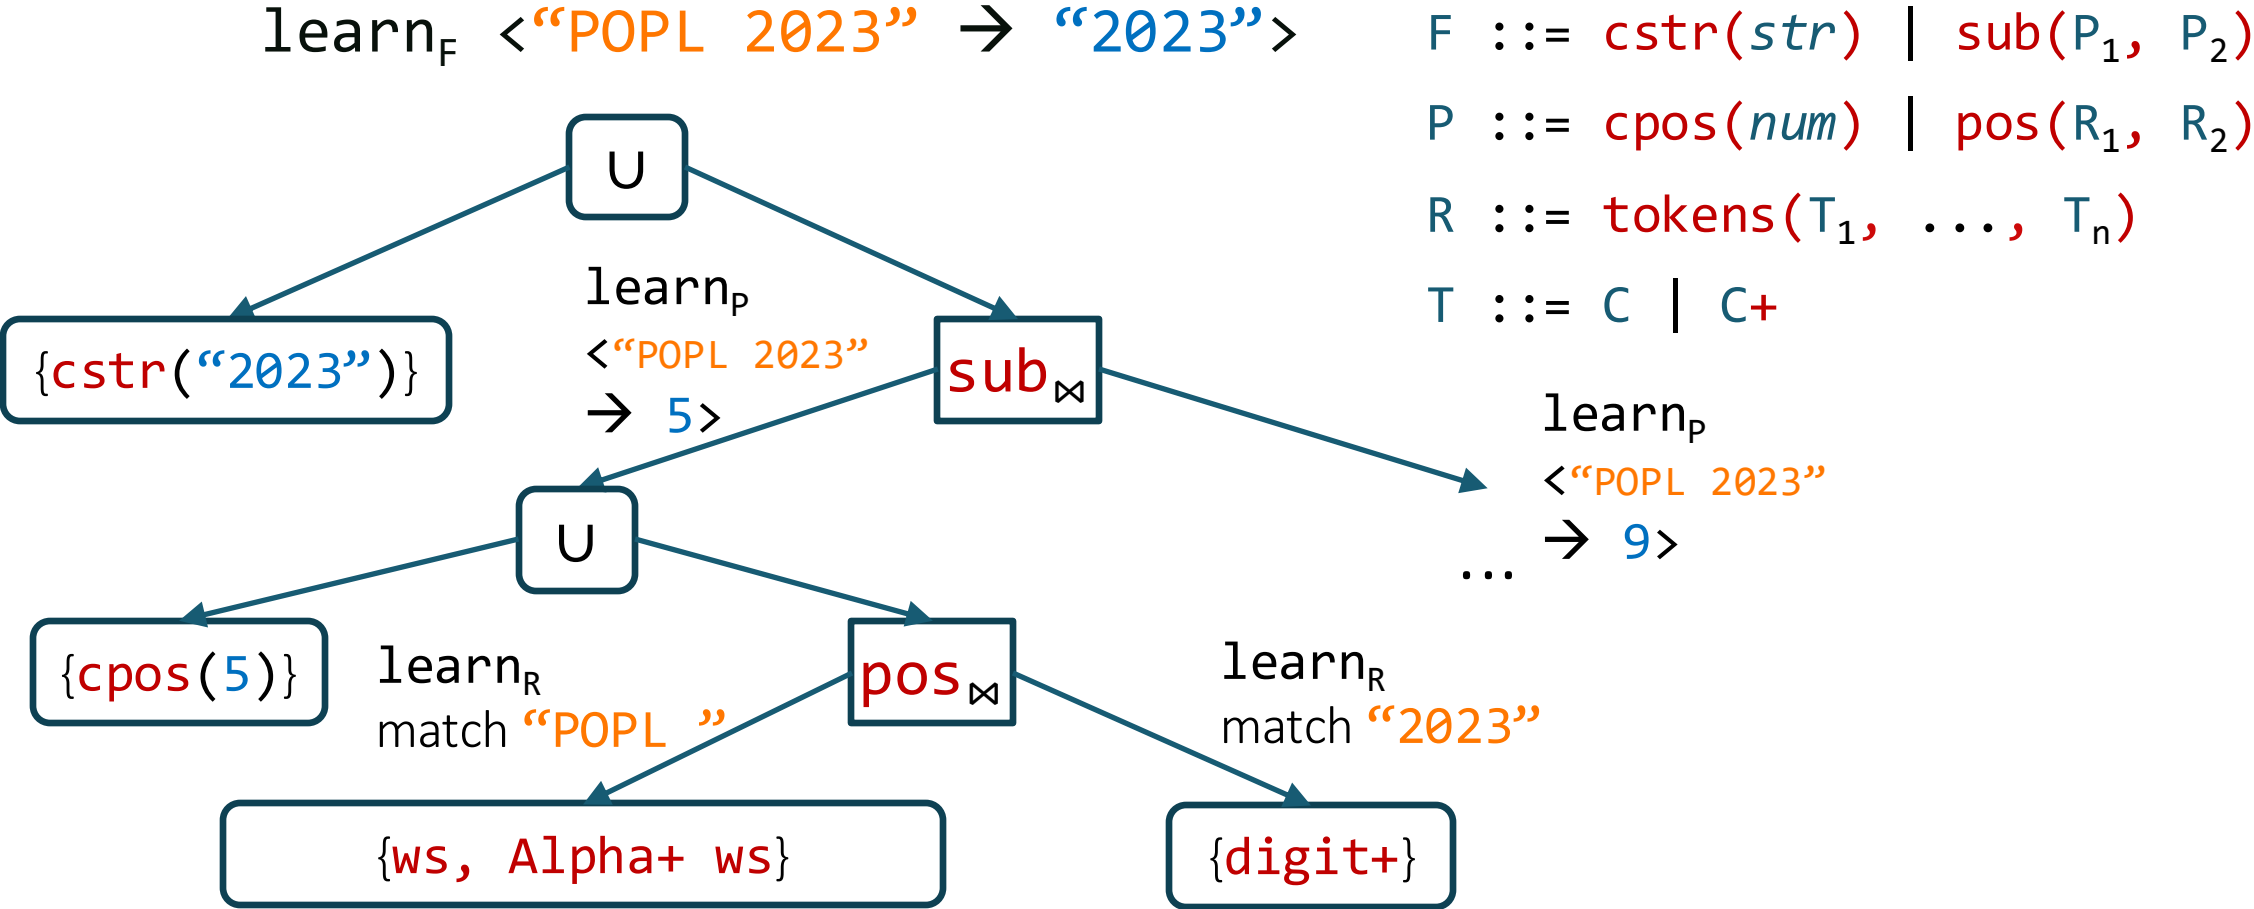

FlashFill: example

"Hello POPL 2023" → "POPL'2023"
"Goodbye PLDI 2021" → "PLDI'2021"

```
concat(
  sub(pos(ws, Alpha), pos(Alpha, ws)),
  concat(
    cstr("'"),
    sub(pos(ws, digit), pos(digit, $))))
```
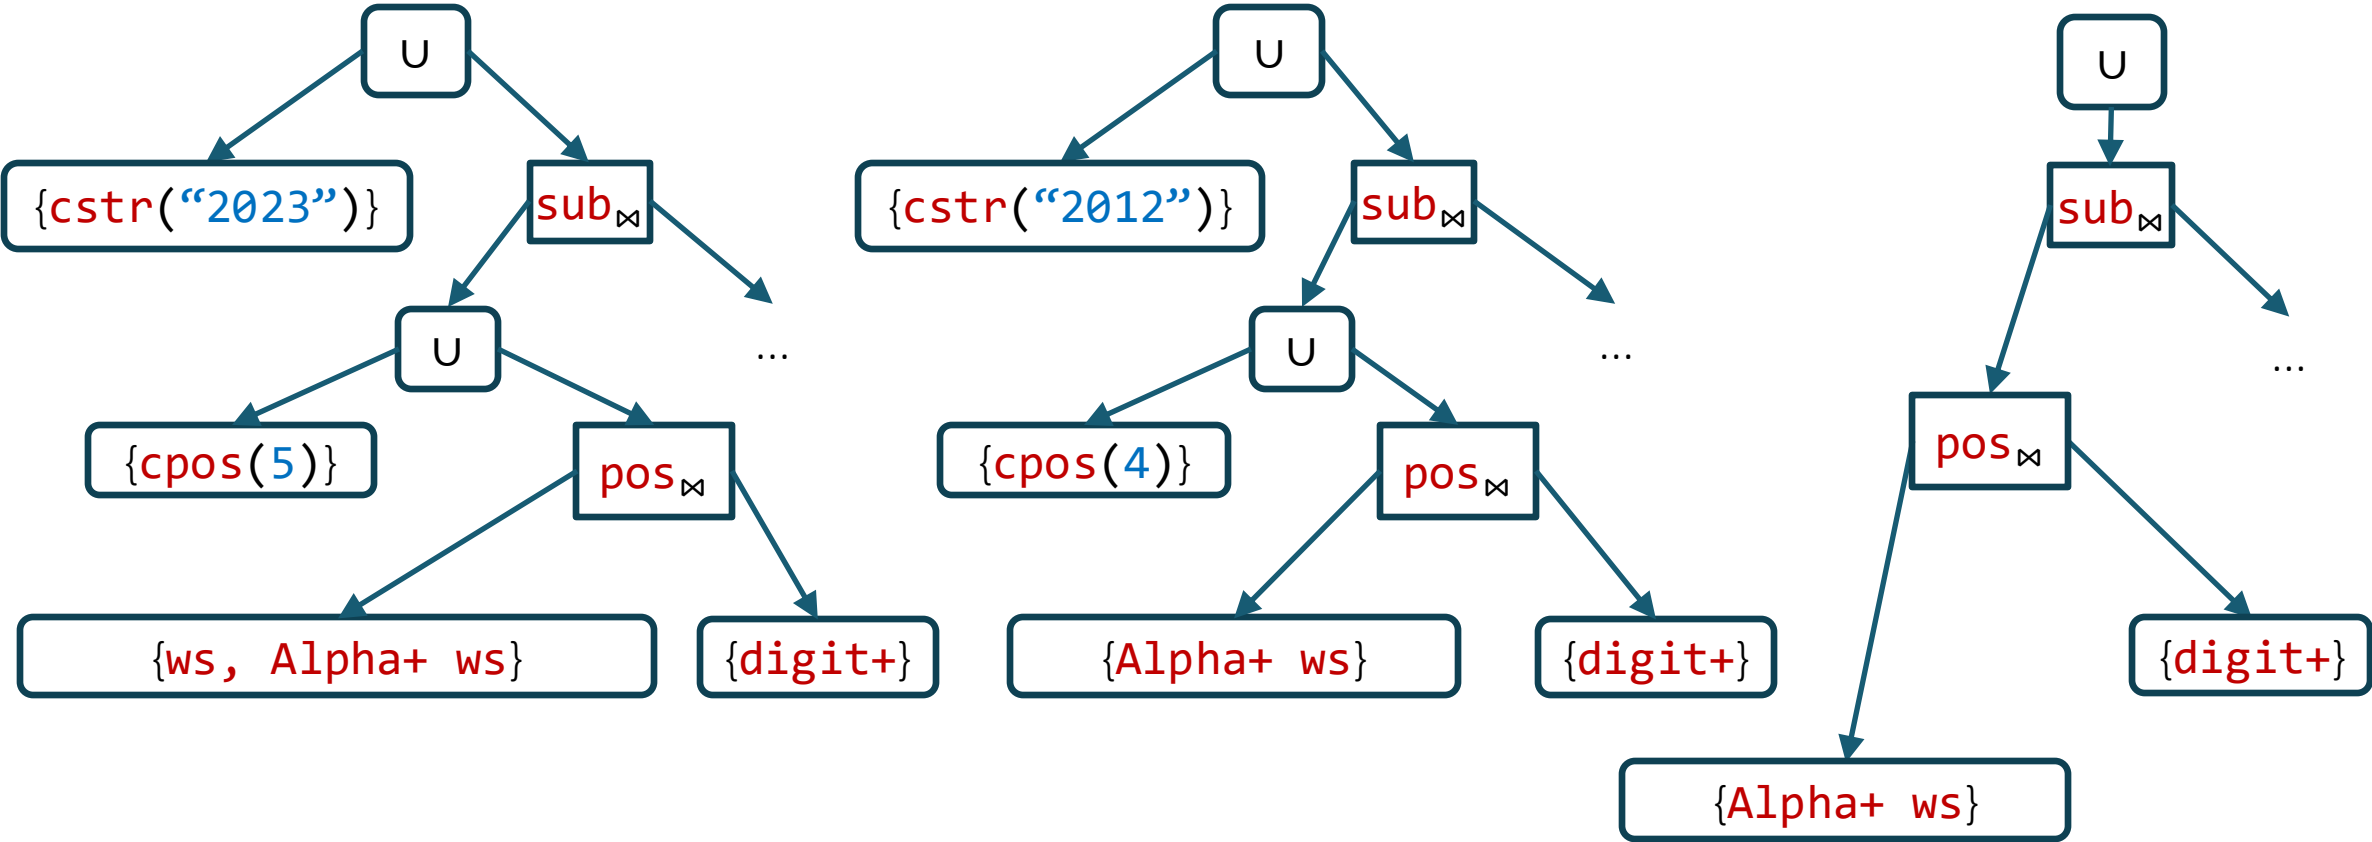

$E ::= F \mid concat(F, E)$

$F ::= cstr(str) \mid sub(P, P)$

$P ::= cpos(num) \mid pos(R, R)$

$R ::= tokens(T_1, ..., T_n)$

$T ::= C \mid C+$

Learning atomic expressions

learn_F <"POPL 2023" → "2023">

F ::= cstr(*str*) | sub(P$_1$, P$_2$)

P ::= cpos(*num*) | pos(R$_1$, R$_2$)

R ::= tokens(T$_1$, ..., T$_n$)

T ::= C | C+

U

learn_P <"POPL 2023" → 5>

sub$_\bowtie$

learn_P <"POPL 2023" ... → 9>

{cstr("2023")}

U

{cpos(5)}

learn_R match "POPL "

pos$_\bowtie$

learn_R match "2023"

{ws, Alpha+ ws}

{digit+}

Intersection

"POPL 2023" → "2023"   " FM 2012" → "2012"

Learning trace expressions

$\text{learn}_E \; \langle \text{"POPL 2023"} \rightarrow \text{"'23"} \rangle$

```
E ::= F | concat(F, E)
F ::= ...
```
Learning trace expressions

learn$_E$ <"POPL 2023" → "'23">

E ::= F | concat(F, E)

F ::= ...
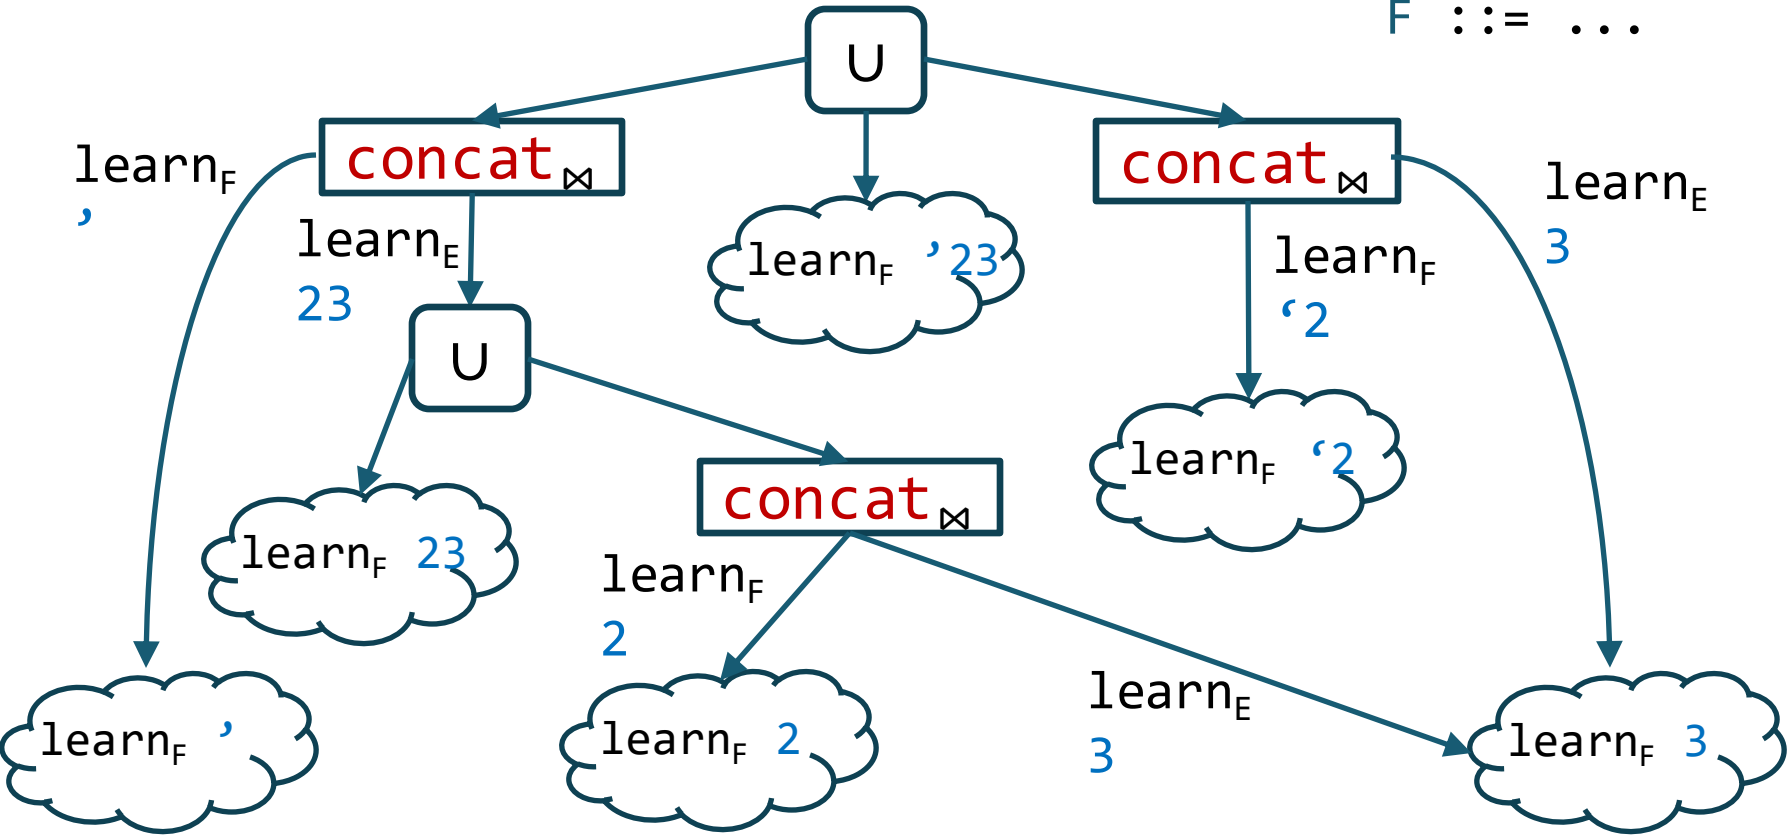

Discussion

Why could we build a finite representation of all expressions?

- Could we do it for this language?

$$E ::= F + F$$

$$F ::= k \mid x$$

$k \in \mathbb{Z}$ + is integer addition

- What about this language?

$$B ::= x \mid !B \mid B \ \& \ B$$

B is a bit-vector

VSA: DSL restrictions

Every operator has a small, easily computable inverse

- Example when an inverse is small but hard to compute?

Every recursive rule generates a strictly smaller subproblem

```
E ::= F | concat(F, E)
```

learn_E '18

concat $_\bowtie$

learn_F ' learn_E 18

PROSE

Ranking function

`r :: Program -> Int`

Grammar

```
A ::= f(B, C) | ...
B ::= g(D, E) | ...
```

Semantics

```
f :: (B, C) -> A
f (b, c) = ...
```

Inverse semantics

```
f⁻¹ :: A -> {(B, C)}
f⁻¹ a = ...
```

Discussion

What do VSAs remind you of in the enumerative world?

- VSA ~ top-down search with top-down propagation

How are they different?

- Caching of sub-problems (DAG!)
- Easier to return a ranked list
- Can construct one per example and intersect

Representations

Version Space Algebra (VSA)

Finite Tree Automaton (FTA)

Type Transition Net (TTN)

Example

Grammar   Spec

N ::= id(V) | N + 2 | N + 3 | N * T   1 → 9

~~T ::= 2 | 3~~

V ::= x

Finite Tree Automata

$\langle A, \mathbb{Z} \rangle$
$A \in \{N, T, X\}$

$\{\langle N, 9 \rangle\}$

states

final states

$$\mathcal{A} = \langle Q, F, Q_f, \Delta \rangle$$

alphabet

transitions

`id, +, *`

$f(q_1, \dots, q_n) \to q$

`+(<N,1>,<T,2>) → <N,3>`

$\dots$

Finite Tree Automata

[Wang, Dillig, Singh OOPSLA'17]

N ::= id(V) | N + T | N * T ◯

T ::= 2 | 3 ▢

V ::= x ◇

1 → 9
Discussion

What do FTAs remind you of in the enumerative world?
- FTA ~ bottom-up search with OE

How are they different?
- More size-efficient: sub-terms in the bank are replicated, while in the FTA they are shared
- Hence, can store all terms, not just one representative per class
- Can construct one FTA per example and intersect

Abstract FTA

Challenge: FTA still has too many states

Idea:
- instead of one state = one value
- we can do one state = set of values (= abstract value)

Abstract FTA
N ::= id(V) | N + T | N * T ◯

T ::= 2 | 3 ▢

V ::= x ◇

1 → 9
What now?

- idea 1: enumerate from reduced space
- idea 2: refine abstraction!

Abstract FTA

N ::= id(V) | N + T | N * T ◯

T ::= 2 | 3 ▢

V ::= x ◇

solution: id(x)
1 → 9

Predicates: {even, < 3, …}
solution: id(x)*3

VSA vs FTA vs E-Graphs

BlinkFill

What does BlinkFill use as behavioral constraints? Structural constraints? Search strategy?

- input-output examples (+ input examples); custom string DSL; VSA

What is the main technical insight of BlinkFill wrt FlashFill?

- BlinkFill uses the available inputs (with no outputs) to infer structure (segmentation) common to all inputs
- it uses this structure to shrink the DAG and to rank substring expressions

Example

learn_F <"Mumbai, India" → "India">

"Los Angeles, United States"

U

{cstr("India")}

learn_P
<"Mumbai, India"
→ 9>

sub$_{\bowtie}$

...

U

{cpos(9)}

ranked higher

("Mumbai, ", 1, End)

(", ", 1, End)

(ws, 1, End)

BlinkFill

Write a BlinkFill program that satisfies:

- "Programming Language Design and Implementation (PLDI), 2019, Phoenix AZ" -> "PLDI 2019"
- "Principles of Programming Languages (POPL), 2020, New Orleans LA" -> "POPL 2020"

- Between first parentheses and between first and last comma:
  ```
  Concat(SubStr(v1, ("(", 1, End), (")",1, Start)),
         SubStr(v1, (",", 1, End), (",", -1, Start)))
  ```

BlinkFill

Could we extend the algorithm to support sequences of tokens?

- More expressive:
  - "Programming Language Design and Implementation: PLDI 2019" -> "PLDI 2019"
  - "POPL 2020 started on January 22" -> "POPL 2020"
  - `SubStr(v1, (C ws d, 1, Start), (C ws d, 1, End))`

Can we change the intersection instead?

- Each edge of the single-string IDG would have more labels
- Extra edges from 0 and to the last node
- More edges left after intersection (might be a problem, but unclear)
- Need fewer primitive tokens (no need for ProperCase)

BlinkFill

Strengths? Weaknesses?

- differences between FlashFill and BlinkFill language? which one is more expressive?
